

The Attention Compiler

Transforming Congestion into Epistemic Progress

The Fundamental Asymmetry of Intellectual Communication

The Illusion

The Illusion: Digital communication scales access infinitely, treating every submission as identical.

The Reality

The Reality: The recipient must repeatedly reconstruct the exact same conceptual path for each message, resulting in the repeated loss of prior cognitive labor.

The Technical Precedent: Thin-Walled Routing

Grounding the solution in Monica Anderson's content-routed chat architectures.

The Evolution of Routing

Traditional

contextual stream

**Concentrated packet
of residual novelty**

The Attention Compiler Pipeline

The Archive as an Executable Map

Decomposing static texts into questions, distinctions, arguments, and counterexamples.

Before: Passive Storage

After: Active Routing

Prerequisite-Sensitive Routing

“A participant passes a conceptual gate by accurately understanding a distinction, not by agreeing with the system or its author. Collapsing that difference turns routing into ideological screening.”

Adaptive Competency Graphs

Linear Curriculum

Fixed courses. Attend and complete before returning.

Competency Graph

Competency is inferred provisionally from performance transfer, not credential recognition.

Conversational Calibration

Estimating the epistemic state through subtle transfer tasks, not blunt tests.

$$q_{t+1}^* = \arg \max_q [\text{IG}(q) + \alpha \text{Prog}(q) - \beta \text{Burden}(q)]$$

Asking a user to apply a distinction to their own idea simultaneously advances the conversation and reveals their epistemic state without a blunt entrance exam.

Swipe Tuning vs. Diagnostic Routing

Strict Separation: A user who dislikes a proof-heavy explanation has not demonstrated an inability to follow proofs. The system strictly separates presentation preference from conceptual mastery.

Developmental Triage and Adversarial Testing

Unconventional ideas are not held to impossible standards solely because they are strange.

The goal is not to prove the submitter wrong, but to forge the strongest surviving formulation of the contribution before human escalation.

Extracting Residual Novelty

The system evaluates novelty after transformation, not before.

$$\rho(x) = (\rho_s, \rho_f, \rho_e, \rho_c, \rho_a)$$

The Residual: Exactly what remains after known answers, terminological substitutions, and familiar objections are removed.

An idea may use entirely familiar words (low semantic novelty) but represent a genuinely new synthesis (high combinatorial novelty).

The Mathematical Core of Attention

A system cannot solve congestion by discarding everything—that destroys intellectual access. It must balance the equation by dramatically lowering the evaluation cost (C) of escalated items, delivering fully prepared, rigorously tested residuals.

Two Topologies of Power

Broadcast Topology

Power of Transmission: The exclusive right to speak to many.

Triage Topology

Power of Convergence: The exclusive right to decide what is adequately said.

Safeguards against Epistemic Gatekeeping: Visible routing explanations, contestable classifications, and exploration budgets (A_x) are strictly required to prevent self-confirming feedback loops at the convergence point.

Access Through Transformation

Every person may enter, every idea may begin in its native form, and every message must become more intelligible as it approaches the frontier of another person's attention.
